

Comparing CI's and significance tests

- These are <u>different methods</u> for coping with the <u>uncertainty</u> about the true value of a parameter caused by the sampling variation in estimates.
- <u>Confidence interval</u>: A <u>fixed level of confidence</u> is chosen. We determine *a range of possible values* for the parameter that are consistent with the data (at the chosen confidence level).
- <u>Significance test</u>: Only one possible value for the parameter, called the hypothesized value, is tested. We determine the *strength of the evidence* (confidence) provided by the data against the proposition that the hypothesized value is the true value.

lide 10

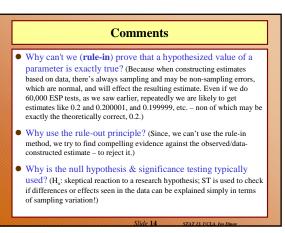

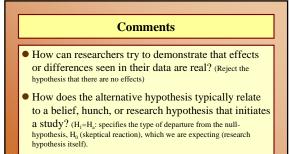

Hypotheses

Guiding principles

We <u>cannot</u> **rule in** a hypothesized value for a parameter, we *can only* determine whether there is evidence *to* **rule out** a hypothesized value.

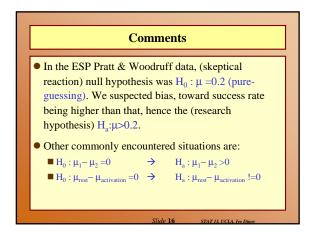

The *null hypothesis* tested is typically a skeptical reaction to a *research hypothesis*

 In the Cavendish's mean Earth density data, null hypothesis was H₀: μ =5.517. We suspected bias, but not bias in any specific direction, hence H_a:μ!=5.517.

Tests and confidence intervals

A *two-sided* test of H_0 : $\theta = \theta_0$ is *significant* at the 5% level <u>if and only if</u> θ_0 lies *outside* a 95% confidence interval for θ .

A *two-sided* test of $H_0: \theta = \theta_0$ gives a result that is significant at the 5% level <u>if</u> the P-value=2Pr(T >=|t_0|) < 0.05. Where $t_0 = (\text{estimate-Hypoth'dValue})/\text{SE}(\theta) \rightarrow t_0 = (\theta' - \theta_0)/\text{SE}(\theta)$. Let **t** be a **threshold** chosen so that Pr(T>=t) = 0.025. Now $|t_0|$ tells us now many SE's θ' and θ are apart (without direction in their diff.) If $|t_0| > t$, then θ_0 is more than **t** SE's away from θ' and hence lies outside the 95% CI for θ .

"Significance"

- *Statistical significance* relates to the <u>strength of the</u> evidence of *existence* of an effect.
- The *practical significance* of an effect depends on its size how large is the effect.
- A small *P*-value provides evidence that the effect *exists* but says *nothing* at all about the *size* of the effect.
- To estimate the *size* of an effect (its practical significance), *compute a confidence interval.*

"Significance" cont.

A non-significant test does not imply that the null hypothesis is true (or that we accept H_0).

It simply means we do not have (this data does not provide) the evidence to reject the skeptical reaction, H_0 .

To prevent people from misinterpreting your report: *Never quote a P-value* about the existence of an effect *without* also *providing a confidence interval* estimating the size of the effect.

Review

- What is the relationship between a <u>95% confidence interval for a parameter θ and the results of a two-sided test of H₀: θ = θ₀? (θ₀ is inside the 95% CI(θ), €
 P-value for the test is >0.025,. Conversely, the test is significan, at 5%-level, €→ θ₀ is outside the 95% CI(θ).
 </u>
- If you read, "research shows that⁰.... is significantly bigger than ...⁰0...", what is a likely explanation? (there is evidence that a real effect exists to make the two values different).
- If you read, "research says that drug, makes no difference to discusser transme", what is a likely explanation? (the data does not have the evidence to reject the skeptical reaction, H₀, or no effects).

Slide 44 STAT 13. UCLA, Ivo Di

Review

- Is a "significant difference" necessarily large or practically important? Why? (No, significant difference indicates the existence of an effect, practical importance depends on the effect-size.)
- What is the difference between statistical significance and practical significance? (stat-significance relates to the strength of the evidence that a real effect exists (e.g., that true difference is not exactly 0); practical significance indicates how important the observed difference is in practice, how large is the effect.)
- What does a *P*-value tell us about the size of an effect? (P-value says whether the effect is significant, but says nothing about its size.)
- What tool do we use to gauge the size of an effect? (Cl(parameter) provides clues to the size of the effect.)

Slide 45

STAT 13 LICLA

• If we read that a difference between two proportions is *non-significant*, what does this tall us? What does it not talls us?

Review

tell us? What does it not tells us? (Do not have evidence proportions are different, based on this data. Doesn't mean accept H₀).
What is the closest you can get to showing that a hypothesized value is true and how could

you go about it? (Suppose, $\underline{H}_0: \underline{\theta} = \underline{\theta}_0$, and our test is notsignificant. To show $\underline{\theta} = \underline{\theta}_0$ we need to show that all values in the $CI(\underline{\theta}_0)$ are essentially equal to $\underline{\theta}_0$, this is a practical subjective matter decision, not a statistical one.)

Slide 46 STAT 13. UCLA. Ivo Di

General ideas of "test statistic" and "p-value"

A *test statistic* is a <u>measure of discrepancy</u> between what we <u>see in data</u> and what we would <u>expect to see</u> if H_0 was true.

The *P-value* is the <u>probability</u>, calculated assuming that the null hypothesis is true, that <u>sampling variation</u> alone would produce data which is <u>more discrepant than our</u> <u>data set</u>.

STAT 13. UCLA. Ivo

Chapter 9 Summary

Significance Tests vs. Confidence Intervals

- The main use of significance testing is to check whether apparent differences or effects seen in data can be explained away simply in terms of <u>sampling variation</u>. The essential **difference between confidence intervals and significance tests** is as follows:
 - Confidence interval : A range of possible values for the parameter are determined that are consistent with the data at a specified confidence level.
 - Significance test : Only one possible value for the parameter, called the hypothesized value, is tested. We determine the strength of the evidence provided by the data against the proposition that the hypothesized value is the true value.

Hypotheses

- The *null hypothesis*, denoted by H_0 , is the (skeptical reaction) hypothesis tested by the statistical test.
- Principle guiding the formulation of null hypotheses: We cannot rule a hypothesized value in; we can only determine whether there is <u>enough evidence to rule it</u> <u>out</u>. Why is that?
- *Research (alternative) hypotheses* lay out the conjectures that the research is designed to investigate and, if the researchers hunches prove correct, establish as being true.

Slide 50 STAT 13. UCLA, Ivo Di

Example: Is there racial profiling or are there confounding explanatory effects?!?

• The book by Best (Danned Lies and Statistics: Untangling Numbers from the Media, Politicians and Activists, Joel Best) shows how we can test for racial bias in police arrests. Suppose we find that among 100 white and 100 black youths, 10 and 17, respectively, have experienced arrest. This may look plainly discriminatory. But suppose we then find that of the 80 middle-class white youths 4 have been arrested, and of the 50 middle-class black youths 2 arrested, whereas the corresponding numbers of lower-class white and black youths arrested are, respectively, 6 of 20 and 15 of 50. These arrest rates correspond to 5 per 100 for white and 4 per 100 for black <u>middle-class</u> youths. Now, better analyzed, the <u>data suggest</u> effects of social class, not race as such.

Hypotheses cont.

- The *null hypothesis* tested is typically a skeptical reaction to the research hypothesis.
- The most commonly tested null hypotheses are of the "it makes no difference" variety.
- Researchers try to demonstrate the existence of real treatment or group differences by showing that the idea that there are no real differences is implausible.
- The *alternative hypothesis*, denoted by *H*₁, specifies the type of <u>departure</u> from the null hypothesis, *H*₀, that we expect to detect.

Slide 52 STAT 13. UCLA. Ivo Di

Hypotheses cont.

- The *alternative hypothesis*, typically corresponds to the research hypothesis.
- We use *one-sided alternatives* (using either : H₁: θ > θ₀ or H₁: θ < θ₀) when the research hypothesis specifies the <u>direction of the effect</u>, or more generally, when the investigators had good grounds for believing the true value of θ was on one particular side of θ₀ before the study began. Otherwise a *two-sided alternative*, H₁: θ ≠ θ₀, is used.

P-values

- Differences or effects seen in data that are easily explainable in terms of sampling variation <u>do not</u> <u>provide convincing evidence</u> that real differences or effects exist.
- The *P*-value is the probability that, if the hypothesis was true, sampling variation would produce an estimate that is further away from the hypothesized value than the estimate we got from our data.
- The *P*-value <u>measures the strength of the evidence</u> <u>against H_{0} </u>.

le 54

*P***-values cont.**

- The *smaller* the *P*-value, the stronger the evidence against *H*₀.
- A large *P*-value provides no evidence against the null hypothesis.
- A large *P*-value does *not* imply that the null hypothesis is true.
- A small *P*-value provides evidence that the effect exists but says *nothing* at all about the *size* of the effect.
- To estimate the **size** of an effect, *compute a confidence interval.*

Slide 55 STAT 13. UCLA. Ivo

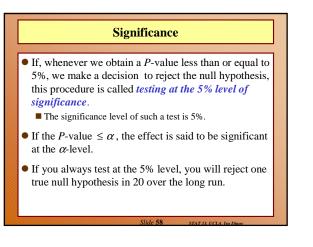

P-values cont. Never quote a *P*-value about the existence of an effect without also providing a confidence interval estimating the size of the effect. Suggestions for verbal translation of *P*-values are given in Table 9.3.2. Computation of *P*-values : Computation of *P*-values for situations in which the sampling distribution of (θ - θ₀)/se(θ), is well approximated by a Student(df) distribution or a Normal(0,1) distribution is laid out in Table 9.3.1. The *t*-test statistic tells us how many standard errors the estimate is from the hypothesized value.

P-values

- Examples given in this chapter concerned means and differences between means, proportions and differences between proportions.
- In general, a test statistic is a measure of discrepancy between what we see in the data and what we would have expected to see if *H*₀ was true.

de 57

STAT 13 UCLA I

Significance cont.

- A two-sided test of $H_0: \theta = \theta_0$ is significant at the 5% level if and only if θ_0 lies outside a 95% confidence interval for θ .
- In reports on research, the word "significant" used alone often means "significant at the 5% level" (i.e. Pvalue ≤ 0.05). "Non-significant", "does not differ significantly" and even "is no different" often mean *P*-value > 0.05.
- A non-significant result does not imply that H_0 is true.

e 59

STAT 13 UCLA

Significance cont.

- A Type I error (false-positive) is made when one concludes that a true null hypothesis is false.
- The significance level is the probability of making a Type I error.
- *Statistical significance* relates to having evidence of the *existence* of an effect.
- The *practical significance* of an effect depends on its *size*.
