

TAT 13. UCLA. Ivo Dino

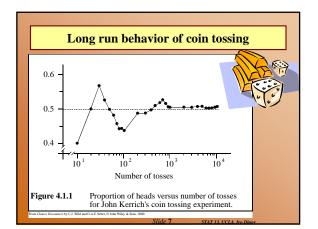

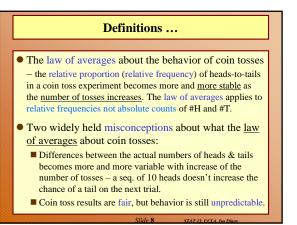

Let's Make a Deal Paradox.

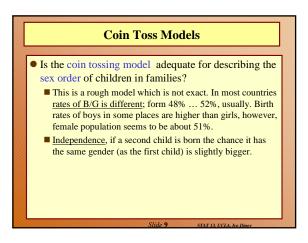

- The *intuition* of most people tells them that each of the doors, the chosen door and the unchosen door, are equally likely to contain the prize so that there is a 50-50 chance of winning with either selection? This, however, is **not the case**.
- The probability of winning by using the switching technique is 2/3, while the odds of winning by not switching is 1/3. The easiest way to explain this is as follows:

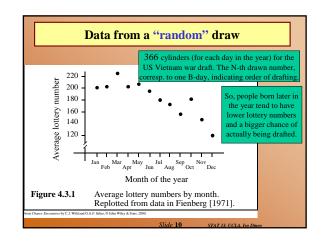

Let's Make a Deal Paradox.

- The probability of picking the wrong door in the initial stage of the game is 2/3.
- If the contestant picks the wrong door initially, the host must reveal the remaining empty door in the second stage of the game. Thus, if the contestant switches after picking the wrong door initially, the contestant will win the prize.
- The probability of winning by switching then reduces to the probability of picking the wrong door in the initial stage which is clearly 2/3.

- Probability models have two essential components (*sample space*, the space of all possible outcomes from an experiment; and a list of *probabilities* for each event in the sample space). Where do the outcomes and the probabilities come from?
- <u>Probabilities from models</u> say mathematical/physical description of the sample space and the chance of each event. Construct a fair die tossing
- <u>Probabilities from data</u> data observations determine our probability distribution. Say we toss a coin 100 times and the observed Head/Tail counts are used as probabilities.
- <u>Subjective Probabilities</u> combining data and psychological factors to design a reasonable probability table (e.g., gambling, stock market).

Review

- What is a sample space? What are the <u>two essential</u> <u>criteria</u> that must be satisfied by a possible sample space? (completeness – every outcome is represented; and uniqueness – no outcome is represented more than once.
- What is an event? (collection of outcomes)
- If A is an event, what do we mean by its complement, \overline{A} ? When does \overline{A} occur?
- If *A* and *B* are events, when does *A* or *B* occur? When does *A* and *B* occur?

Summary

- What does it mean for two events *A* and *B* to be *statistically independent*?
- Why is the working rule under independence, P(A and B) = P(A) P(B), just a special case of the multiplication rule P(A & B) = P(A | B) P(B)?
- Mutual independence of events $A_1, A_2, A_3, ..., A_n$ if and only if $P(A_1 \& A_2 \& ... \& A_n) = P(A_1)P(A_2)...P(A_n)$
- What do we mean when we say two human characteristics are *positively associated? negatively* associated? (blond hair – blue eyes, pos.; black hair – blue eyes, neg.assoc.)

. 40

STAT 13 UCLA

Review• Other the predict of the calculated P(A and B) if we treat positively associated events as independent? If we treat negatively associated events as independent? If we treat negatively associated events as independent? (Example, let B={A + {b}}, A & B are neg-assoc'd, P(A&B)=P(A)(P(A)+P((b))), under indep. assump's. However, P(A&B)=P(A)(P(A)+P((b))), under indep. assump's. However, P(A&B)=P(A)(P(A)+P((b))), under indep. assoc'd - A & comp(B) are predicted events as independent? If A & B are neg-assoc'd - A & comp(B) are predicted events. If A & B are neg-assoc'd - A & comp(B) are predicted events as independent? If A & B are neg-assoc'd - A & comp(B) are predicted events. If A & B are neg-assoc'd - A & comp(B) are predicted eve

Summary of ideas

- The *probabilities* people quote come from 3 main sources:
 (i) *Models* (idealizations such as the notion of equally
 - likely outcomes which suggest probabilities by symmetry).(ii) *Data* (e.g. relative frequencies with which the event has occurred in the past).
 - (iii) *subjective feelings* representing a degree of belief
- A simple probability model consists of a sample space and a probability distribution.
- A sample space, *S*, for a random experiment is the set of all possible outcomes of the experiment.

Slide 51

STAT 13 LICLA I

Summary of ideas cont. A list of numbers p₁, p₂, ... is a *probability distribution* for S = {s₁, s₂, s₃, ...}, provided all of the p_i's lie between 0 and 1, and they add to 1. According to the probability model, p_i is the probability that outcome s_i occurs. We write p_i = P(s_i).

ilide 52 STAT 13 UCLA. Ivo Di

Summary of ideas cont.

- An event is a collection of outcomes
- An event *occurs* if any outcome making up that event occurs
- The probability of event A can be obtained by adding up the probabilities of all the outcomes in A
- If all outcomes are equally likely,

$pr(A) = \frac{\text{number of outcomes in } A}{\text{total number of outcomes}}$
