Chapter 7: Sampling Distributions

- Parameters and Estimates
- •Sampling distributions of the sample mean
- •Central Limit Theorem (CLT)
- •Estimates that are approximately Normal
- Standard errors of differences
- Student's t-distribution

Parameters and estimates

- A *parameter* is a numerical characteristic of a population or distribution
- An *estimate* is a quantity calculated from the data to <u>approximate</u> an **unknown** parameter
- Notation
 Capital letters refer to random variables
 - Small letters refer to observed values
 - ide **4** STAT 13 UCLA Ina Dia

Questions

- What are two ways in which random observations arise and give examples. (random sampling from finite population – randomized scientific experiment; random process producing data.)
- What is a parameter? Give two examples of parameters. (characteristic of the data – mean, 1st quartile, std.dev.)
- What is an estimate? How would you estimate the parameters you described in the previous question?
- What is the distinction between an estimate (p^ value calculated form obs'd data to approx. a parameter) and an estimator (P^ abstraction the the properties of the ransom process and the sample that produced the estimate)? Why is this distinction necessary? (effects of sampling variation in P^)

Central Limit Theorem – theoretical formulation

Let $\{X_1, X_2, ..., X_k, ...\}$ be a sequence of independent observations from one specific random process. Let and $E(X) = \mu$ and $SD(X) = \sigma$ and both are finite $(0 < \sigma < \infty; |\mu| < \infty)$. If $\overline{X}_n = \frac{1}{n} \sum_{k=1}^n X_k$, sample-avg, Then \overline{X} has a <u>distribution</u> which approaches

 $N(\mu, \sigma^2/n)$, as $n \to \infty$.

Slide 22 STAT 13. UCLA. Ivo Dine

Review

- What does the central limit theorem say? Why is it useful? (If the sample sizes are large, the mean in Normally distributed, as a RV)
- In what way might you expect the central limit effect to differ between <u>samples from a symmetric</u> distribution and <u>samples from a very skewed</u> <u>distribution</u>? (Larger samples for non-symmetric distributions to see CLT effects)
- What other important factor, apart from skewness, slows down the action of the central limit effect?

(Heavyness in the tails of the original distribution.)

23 STAT 13. UCLA. Is

Review When you have data from a moderate to small sample and want to use a normal approximation to the distribution of *X̄* in a calculation, what would you want to do before having any faith in the results? (30 or more for the sample-size, depending on the skewness of the distribution of *X*. Plot the data - non-symmetry and heavyness in the tails slows down the CLT effects). Take-home message: CLT is an application of statistics of paramount importance. Often, we are not sure of the distribution of an observable process. However, the CLT gives us a theoretical description of the distribution of the sample means as the sample-size increases (N(µ, σ²m)).

The standard error of the mean - remember ...

- For the sample mean calculated from a random sample, SD(\overline{X}) = $\frac{\sigma}{\sqrt{n}}$. This implies that the variability from sample to sample in the *sample-means* is given by the variability of the individual observations divided by the square root of the sample-size. In a way, averaging decreases variability.
- Recall that for *known* SD(X)= σ , we can express the SD(\overline{X}) = $\frac{\sigma}{\sqrt{n}}$. How about if SD(X) is *unknown*?!?

Sampling distribution of the sample proportion

The sample proportion \hat{p} estimates the population proportion p.

Suppose, we poll college athletes to see what percentage are using performance inducing drugs. If 25% admit to using such drugs (in a single poll) can we trust the results? What is the variability of this proportion measure (over multiple surveys)? Could Football, Water Polo, Skiing and Chess players have the same drug usage rates?

Slide 32

Review

- In the TV show Annual People's Choice Awards, awards are given in many categories (including favorite TV comedy show, and favorite TV drama) and are chosen using a Gallup poll of 5,000 Americans (US population approx. 260 million).
- At the time the 1988 Awards were screened in NZ, an NZ Listener journalist did "a bit of a survey" and came up with a list of awards for NZ (population 3.2 million).
- Her list differed somewhat from the U.S. list. She said, "it may be worth noting that in both cases approximately 0.002 percent of each country's populations were surveyed." The reporter inferred that because of this fact, her survey was just as reliable as the Gallup poll. Do you agree? Justify your answer. (only 62 people surveyed, but that's day. Popula deduce using survey).

Slide 39 STAT 13 UCLA IN

Review

 A 1997 questionnaire investigating the opinions of computer hackers was available on the internet for 2 months and <u>attracted</u> 101 responses, e.g. 82% said that stricter criminal laws would have no effect on their activities. Why would you have no faith that a 2 std-error interval would cover the true proportion?
 (sampling errors present (self-selection), which are a lot larger than nonsampling statistical random errors). **Bias and Precision** • The bias in an estimator is the <u>distance</u> between between the <u>center</u> of the sampling distribution of the <u>estimator</u> and the <u>true value of the parameter</u> being estimated. In math terms, bias = $E(\hat{\Theta}) - \theta$, where theta $\hat{\Theta}$ is the estimator, as a RV, of the true (unknown) parameter $\hat{\theta}$. • Example, Why is the sample mean an <u>unbiased</u> estimate for the population mean? How about ³/₄ of the sample mean? $E(\hat{\Theta}) - \mu = E\left(\frac{31}{4n}\sum_{k=1}^{n} x_k\right) - \mu =$ $E(\hat{\Theta}) - \mu = E\left(\frac{1}{n}\sum_{k=1}^{n} x_k\right) - \mu = 0$ $\frac{3}{4}\mu - \mu = \frac{\mu}{4} \neq 0$, in general. Stilde 42 State LICLA to Binst

Standard error of a difference of proportions
Standard error for a difference between independent
estimates:

$$SE(\hat{p}_1 - \hat{p}_2) = \sqrt{\frac{0.52 \times 0.48}{139} + \frac{0.29 \times 0.71}{378}} = 0.04838$$
So the estimated difference give/take 2SE's is:

$$\hat{p}_1 - \hat{p}_2 \pm 2 \times 0.04838 = [0.13; 0.33]$$

Review

- Qualitatively, how does the Student (*df*) distribution differ from the standard Normal(0,1) distribution? What effect does increasing the value of df have on the shape of the distribution? (*σ* is replaced by SE)
- What is the relationship between the Student (df=∞) distribution and the Normal(0,1) distribution? (Approximates N(0,1) as n→increases)

Review

- Why is *T*, the number of standard errors separating *X̄* and μ, a more variable quantity than Z, the number of standard deviations separating *X̄* and μ? (Since an additional source of variability is introduced in T, SE, not available in Z. E.g., P(-2<=T<2)=0.9144 < 0.954=P(-2<=Z<2), hence tails of T are wider. To get 95% confidence for T we need to go out to +/-2.365).
- For large samples the true value of μ lies inside the interval $\overline{x} \pm 2 \operatorname{se}(\overline{x})$ for a little more than 95% of all samples taken. For small samples from a normal distribution, is the proportion of samples for which the true value of μ lies within the 2-standard-error interval smaller or bigger than 95%? Why?smaller-wider util.

Review

- For a small Normal sample, if you want an interval to contain the true value of μ for 95 % of samples taken, should you take more or fewer than two-standard errors on either side of x̄ ? (more)
- Under what circumstances does mathematical theory show that the distribution of $T=(\overline{X}-\mu)/SE(\overline{X})$ is exactly Student (*df=n-1*)? (Normal samples)
- Why would methods derived from the theory be of little practical use if they stopped working whenever the data was not normally distributed? (In practice, we're never sure of Normality of our sampling distribution).

Chapter 7 Summary

Sampling Distributions

- For random quantities, we use a capital letter for the random variable, and a small letter for an observed value, for example, *X* and *x*, \overline{X} and \overline{x} , \hat{P} and \hat{p} , $\hat{\Theta}$ and $\hat{\theta}$.
- In estimation, the random variables (capital letters) are used when we want to think about the effects of sampling variation, that is, about how the random process of taking a sample and calculating an estimate behaves.

Sampling distribution of the
sample proportion
Sample proportion,
$$\hat{P}$$
: For a random sample of size *n*
from a population in which a proportion *p* have a
characteristic of interest, we have the following results about
the sample proportion with that characteristic:

$$\mu_{\hat{p}} = E(\hat{P}) = p \qquad \sigma_{\hat{p}} = sd(\hat{P}) = \sqrt{\frac{p(1-p)}{n}}$$

$$\hat{P}$$
 is approximately Normally distributed for large *n*
(a.g., $w(l, p) \ge 10$, theorem as more accurate rule is given in the part

Student's *t*-distribution

- Is bell shaped and centered at zero like the Normal(0,1), but
- More variable (larger spread and fatter tails).
- As *df* becomes larger, the Student(*df*) distribution becomes more and more like the Normal(0,1) distribution.
- Student(df = ∞) and Normal(0,1) are two ways of describing the same distribution.

Student's t-distribution cont.

• For random samples from a Normal distribution,

$$T = (\overline{X} - \boldsymbol{\mu}) / SE(\overline{X})$$

is exactly distributed as Student(df = n - 1), but methods we shall base upon this distribution for *T* work well even for small samples sampled from distributions which are quite non-Normal.

• By $t_{df}(prob)$, we mean the number *t* such that when $T \sim \text{Student}(df)$, $\text{pr}(T \ge t) = prob$; that is, the tail area above *t* (that is to the right of *t* on the graph) is *prob*.

CLT Example – CI shrinks by half by
quadrupling the sample size!• If I ask 30 of you the question "Is 5 credit hour a reasonable
load for Stat13?", and say, 15 (50%) said *no*. Should we
change the format of the class?• Not really – the 2SE interval is about [0.32; 0.68]. So, we
have little concrete evidence of the proportion of students who
think we need a change in Stat 13 format,
 $\hat{p} \pm 2 \times SE(\hat{p}) = 0.5 \pm 2 \times \sqrt{\frac{\hat{p}(1-\hat{p})}{n}} = 0.5 \pm -0.18$ • If I ask all 300 Stat 13 students and 150 say *no* (still 50%),
then 2SE interval around 50% is: [0.44; 0.56].• So, large sample is much more useful and this is due to
CLT effects, without which, we have no clue how useful
our estimate actually is ...
