A study was conducted on the sleep patterns of infants in the United States. A sample of 36 infants was drawn at random with an average hours slept of 11 hours in a 24-hour period. Suppose the standard

FORM Y

deviation is 1.8 hours.

a. Please compute an approximate 95% confidence interval for the average sleep time of U.S.

FORM Y

infants. (5 points)
$$11 \pm 2 \cdot \left( \frac{36 \cdot 1.8}{36} \right) = 11 \pm .6$$

$$11 - 2 \left( \frac{36}{36} \right) = 11 - 16$$

The next 4 questions are worth 2 points each:

FORM Y

average with 95% confidence, how large should your sample size be? Please show your work. (10 points)  $5 = 2 * \left(\sqrt{n + 1.8}\right)$ 

2. Exercise is particularly beneficial for young adults. A study wants examines the mean number of hours spent exercising per week by college students. Suppose it is known that 30% of all college students exercise weekly. A sample of 25 students is selected by a random process and it is found that a 95% confidence interval for the mean number of hours spent exercising by college students is 2.4 hours to 3.6 hours per week. Using this information, please answer the following true/false questions (4 points each)

	True	False	Statement
A		X	This 95% confidence interval is valid only when the population variable (hours spent exercising per week) is normally distributed.
В		X	This 95% confidence interval is valid only when the sample information (hours spent exercising per week) is normally distributed
С		X	There is a 95% chance that for all college students, the mean hours spent exercising per week is between 2.4 and 3.6 hours per week.
D		X	95% of all college students exercise between 2.4 and 3.6 hours per week.
E		X	The purpose of this 95% confidence interval is to estimate the mean number of hours spent exercising by college students in the sample.
F		X	There is a 95% chance that of the 25 students, the percentage of weekly exercisers will be between approximately 20.8% and 39.2%.
G	X		If we decreased the confidence level to 68%, we would expect the confidence interval get narrower.
H		X	If we quadrupled the sample size, we would expect the 95% confidence interval to be one fourth as wide.

3. (use the information given in question 2 before the true-false questions) A physiology class needs more students for a valid study and a sample of size 25 is not enough. So if 900 college students are chosen at random instead of 25, what is the chance that between 243 and 261 of those chosen do indeed exercise weekly? (8 points)

$$\frac{6x^{pect}}{2^{45}} = \frac{261 - 270}{\sqrt{400} * \sqrt{3} \times .7} \times -1.65$$

$$\frac{7}{243} = \frac{243 - 270}{\sqrt{400} * \sqrt{3} \times .7} \times -1.91$$

$$\frac{94.87 - 48.43}{2} = 23.225\%$$

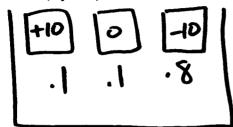

4. A professor made a careful sample survey to estimate the percentage of USC undergraduates living at home. Two assistants were stationed at the "Tommy" Trojan statue (it's on the main plaza) and instructed to interview all students who passed by at specified times. Many students would not speak with the assistants, in fact, only 269 out of 1000 approached, did. As it turned out, 21% of 269 students interviewed said they live at home. Does the investigator's procedure give a probability sample of USC students?

First, answer yes or no and then explain your reasons for your choice. This does not need to be a long answer. (7 points)

No.

Selection Bias (justify) and Non-Response Bias (justify)

- 5. It's a family tradition: your professor goes to Las Vegas every year for Thanksgiving. A new casino has opened and they are playing a modified roulette game that has 40 possible numbers that can be spun on a wheel. To play you bet \$10 and you get to choose 4 numbers. If the wheel lands on any number that you chose, you win \$10. If the wheel does not land on a number you choose but on one of 4 "special numbers" you don't win or lose anything. If the wheel lands on any of the remaining numbers (not the ones you choose or the "special numbers"), you lose your bet of \$10. Suppose the typical person plays 25 times.
- a. This game of modified roulette can be represented by a box model, please construct a reasonable one in the space below (6 points)

b. The 25 plays can be treated like a random sample of size 25. Find the expected value of this game. (4 points)

c. Find the standard error of this game. (4 points)

$$5E = \sqrt{25 * \sqrt{(.1)(10--7)^2 + (.1)(0--7)^2 + (.8)(-10--7)^2}}$$

$$= 32.0156$$

d. Suppose the professor decides to spend \$250 playing a total of 25 times and she lost all of her money. Calculate the chance that your professor could lose at least \$250 playing this game. Show all of your work and answer this question – based on your calculations is she unlucky (let's suppose unlucky means the chance of losing at least \$250 is less than 5%)? (6 points)

$$Z = \frac{-250 - (-175)}{32.0152} = -2.35$$

$$100 - 98.12 = .94\%$$
